Experiment No. 1

Determination of alkalinity of a given water sample

Apparatus Required:
1) Pipette; 2) Conical flask; 3) Burette;
4) Beaker; 5) Funnel, and 6) Stand

Chemicals Required:
1) Methyl orange
2) Phenolphthalein,
3) Standard HCl

Theory:
The alkalinity of water is due to the presence of soluble
a. hydroxides,
b. carbonates, and
c. bicarbonates
of alkali and alkaline earth metals.

With respect to the constituents causing alkalinity in natural waters, the following situation may arise.
1. hydroxides only,
2. carbonates only,
3. bicarbonates only,
4. hydroxide and carbonates,
5. carbonates and bicarbonates.

Note: The possibility of hydroxides and bicarbonates existing together is ruled out owing to the fact that they combine with each other forming the respective carbonates:

\[
\text{OH}^- + \text{HCO}_3^- \rightarrow \text{CO}_3^{2-} + \text{H}_2\text{O}
\]
The type and extent of alkalinity present in the water sample is conveniently determined by titrating an aliquot of the sample with acid using phenolphthalein to detect end-point, (P), and then continuing the titration with methyl orange to another end-point, (M). The reaction-taking place may be represented by the following equations:

\[
\text{OH}^- + \text{H}^+ \rightarrow \text{H}_2\text{O} \quad \ldots \ldots \text{(1)}
\]
\[
\text{CO}_3^{2-} + \text{H}^+ \rightarrow \text{HCO}_3^- \quad \ldots \ldots \text{(2)}
\]
\[
\text{HCO}_3^- + \text{H}^+ \rightarrow \text{H}_2\text{CO}_3 \rightarrow \text{H}_2\text{O} + \text{CO}_2 \quad \ldots \ldots \text{(3)}
\]

The volume of acid run down up to phenolphthalein** end point, (P) corresponds to the completion of reactions (1) and (2) given above while the volume of acid run down after (P) corresponds to the completion of reaction (3). The total amount of acid used from the beginning of the experiment to the end, i.e. (M) corresponds to the total alkalinity and represents the completion of reactions shown by equation (1), (2) and (3).

The results may be summarized in the following Table (1), from which the amount of hydroxides, carbonates and bicarbonates present in the water sample may be computed.

<table>
<thead>
<tr>

Alkalinity is generally expressed as parts per million (ppm) in terms of CaCO\(_3\) or on degrees Clark.

6.... Chemistry Lab Manual
Procedure:

Transfer 100 ml of the water sample into a conical flask, add 1 to 2 drops of phenolphthalein indicator, and titrate the sample with the standard HCl until the pink colour just persisted. Note the titre value as the phenolphthalein end-point, (P). Then add 2 to 3 drops of methyl orange indicator to the same solution and continue the titration until a sharp color change from yellow to red takes place. Note the total titr value from the beginning of the experiment as methyl orange end-point, (M).

Sample Observation:

<table>
<thead>
<tr>
<th>S.No.</th>
<th>Volume of the water sample taken (ml)</th>
<th>Volume of HCl, phenolphthalein end-point, (P), ml</th>
<th>Vol. of HCl, methyl orange end point (M), ml</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>100</td>
<td>20</td>
<td>42</td>
</tr>
<tr>
<td>2</td>
<td>100</td>
<td>18</td>
<td>41</td>
</tr>
<tr>
<td>3</td>
<td>100</td>
<td>18</td>
<td>41</td>
</tr>
</tbody>
</table>

Calculation:

Now, \( (P) = 18 \text{ ml} \) \( (M) = 41 \text{ ml} \) and \( \frac{1}{2} M = 21 \text{ ml} \)

Since \( (P) < \frac{1}{2} (M) \), the sample should contain only \( \text{CO}_3^{2-} \) and \( \text{HCO}_3^- \) and it does not contain \( \text{OH}^- \) (vide Table 1).

Further, \( 2(P) \) should correspond with the volume of HCl with respect to \( \text{CO}_3^{2-} \) and \( (M) - 2(P) \) should correspond with volume of HCl with respect to \( \text{HCO}_3^- \).

Thus, volume of N/50 HCl equivalent to \( \text{CO}_3^{2-} \)

\[ = 2(P) = 2 \times 18 \text{ ml} = 36 \text{ ml} \]

and Volume of N/50 HCl equivalent \( \text{HCO}_3^- \)

\[ = (M) - 2(P) = 41 - (2 \times 18) = 5 \text{ ml} \]
Now,

Normality of the water sample with respect to $\text{CO}_3^{--} \ (N_2) = ?$

since, $V_1N_1 = V_2N_2$

$$N_2 = \frac{V_1N_1}{V_2} = \frac{36 \times \frac{N}{50}}{100}$$

$$= 7.2 \times 10^{-3} \text{ N}$$

Since, Strength = Normality × Equivalent weight (g/l)

Strength of $\text{CO}_3^{--} = 7.2 \times 10^{-3} \text{ N} \times 30 = 0.216 \text{ g/l}$

Strength of $\text{CO}_3^{--}$ in terms of CaCO$_3$

$$= \text{strength of } \text{CO}_3^{--} \times \frac{\text{Equivalent weight of CaCO}_3}{\text{Equivalent weight of CO}_3}$$

$$= 0.216 \times \frac{50}{30} \text{ g/l}$$

$$= 0.36 \text{ g/l} \quad \{1 \text{ g} = 1000 \text{ mg}\}$$

$$= 360 \text{ mg/l} \quad \{1 \text{ mg/l} = 1 \text{ ppm}\}$$

$$= 360 \text{ ppm} \quad \{14.3 \text{ ppm} = 1 \text{ Clark}\}$$

$$= 25.17 \text{ Clark}$$

Similarly,

Normality of water sample with respect to $\text{HCO}_3^{-} \ , \ (N_2) = ?$

since, $V_1N_1 = V_2N_2$
\[ \frac{V_1 N_1}{V_2} = \frac{5 \times \frac{N}{50}}{100} = 10^{-3} \text{ N} \]

Strength of $\text{HCO}_3^-$ = $10^{-3} \times 61 = 0.061 \text{ g/l}$

(Strength = Normality X Eq. Wt. of $\text{HCO}_3^-$)

Strength of $\text{HCO}_3^-$ in terms of $\text{CaCO}_3$

\[ = \text{strength of } \text{HCO}_3^- \times \frac{\text{Equivalent weight of } \text{CaCO}_3}{\text{Equivalent weight of } \text{HCO}_3^-} \]

\[ = 0.061 \times \frac{50}{61} \]

\[ = 0.05 \text{ g/l} \]

\[ = 50 \text{ mg/l} \]

\[ = 50 \text{ ppm} \]

Results:

Alkalinity with respect to $\text{CO}_3^{2-}$ in terms of $\text{CaCO}_3 = 360 \text{ ppm} = 25.17 \text{ Clark}$

Alkalinity with respect to $\text{HCO}_3^-$ in terms of $\text{CaCO}_3 = 50 \text{ ppm} = 3.5 \text{ Clark}$

Total alkalinity in terms of $\text{CaCO}_3 = 410 \text{ ppm} = 28.67 \text{ Clark}$
